A function in Excel is a predefined formula that performs a specific task and returns a value. It can be created by using the "Insert Function" feature or by typing the function directly into a cell. Functions in Excel are useful for performing complex calculations and data analysis. They can also be customized and combined with other functions to create more advanced formulas. By understanding how to create and use functions in Excel, users can efficiently manipulate data and streamline their spreadsheet processes.

This article describes the formula syntax and usage of the **T** function in Microsoft Excel.

Description

Returns the text referred to by value.

Syntax

T(value)

The T function syntax has the following arguments:

Value Required. The value you want to test.

Remarks

If value is or refers to text, T returns value. If value does not refer to text, T returns "" (empty text).

You do not generally need to use the T function in a formula because Microsoft Excel automatically converts values as necessary. This function is provided for compatibility with other spreadsheet programs.
