## RECOMMENDED CITATION

stats writer (2024). *How can I stack multiple Pandas DataFrames together?*.

PSYCHOLOGICAL SCALES. Retrieved from <https://scales.arabpsychology.com/?p=136791>

Stacking multiple Pandas DataFrames together refers to the process of combining or merging multiple DataFrames into one larger DataFrame. This can be achieved by using the built-in Pandas functions such as `concat`, `merge`, and `join`. These functions allow for the combination of DataFrames based on common columns or indexes, resulting in a single comprehensive DataFrame. This approach is useful for organizing and analyzing large datasets, as it allows for easier manipulation and comparison of data. By stacking DataFrames together, users can efficiently handle and analyze complex datasets in a structured and organized manner.

## Stack Multiple Pandas DataFrames

Often you may wish to stack two or more pandas DataFrames. Fortunately this is easy to do using the pandas `concat()` function.

This tutorial shows several examples of how to do so.

### Example 1: Stack Two Pandas DataFrames

The following code shows how to "stack" two pandas DataFrames on top of each other and create one DataFrame:

```
import pandas as pd

#create two DataFrames
df1 = pd.DataFrame({'player': ,
'points':})

df2 = pd.DataFrame({'player': ,
```

```
'points':})
```

```
#"stack" the two DataFrames together
```

```
df3 = pd.concat(, ignore_index=True)
```

```
#view resulting DataFrame
```

```
df3
```

```
player points
```

```
0 A 12
```

```
1 B 5
```

```
2 C 13
```

```
3 D 17
```

```
4 E 27
```

```
5 F 24
```

```
6 G 26
```

```
7 H 27
```

```
8 I 27
```

```
9 J 12
```

**Example 2: Stack Three Pandas DataFrames**

**Similar code can be used to stack three pandas DataFrames on top of each other to create one DataFrame:**

```
import pandas as pd
```

```
#create three DataFrames
```

```
df1 = pd.DataFrame({'player': ,  
'points':})
```

```
df2 = pd.DataFrame({'player': ,  
'points':})
```

```
df3 = pd.DataFrame({'player': ,  
'points':})
```

```
#"stack" the two DataFrames together
```

```
df4 = pd.concat(, ignore_index=True)
```

```
#view resulting DataFrame
```

```
df4
```

```
player points
```

```
0 A 12
```

```
1 B 5
```

```
2 C 13
```

```
3 D 17
```

```
4 E 27
```

```
5 F 24
```

```
6 G 26
```

**10 K 9**

**11 L 5**

**12 M 5**

**13 N 13**

**14 O 17**

The Importance of `ignore_index`

Note that in the previous examples we used `ignore_index=True`.

This tells pandas to ignore the index numbers in each DataFrame and to create a new index ranging from 0 to n-1 for the new DataFrame.

For example, consider what happens when we don't use `ignore_index=True` when stacking the following two DataFrames:

```
import pandas as pd
```

```
#create two DataFrames with indices
```

```
df1 = pd.DataFrame({'player': ,
```

```
'points':},  
index=)
```

```
df2 = pd.DataFrame({'player': ,  
'points':},  
index=)
```

```
#stack the two DataFrames together
```

```
df3 = pd.concat()
```

```
#view resulting DataFrame
```

```
df3
```

```
player points
```

```
0 A 12
```

```
1 B 5
```

```
2 C 13
```

```
3 D 17
```

```
4 E 27
```

```
2 F 24
```

```
4 G 26
```

```
5 H 27
```

```
6 I 27
```

```
9 J 12
```

**The resulting DataFrame kept its original index values from the two DataFrames.**

**Thus, you should typically use `ignore_index=True` when stacking two DataFrames unless you have a specific reason for keeping the original index values.**
