`Str_match` is a function in the programming language R that allows users to search for specific patterns within a string of characters. This function can be useful for data manipulation and analysis as it allows for the extraction of relevant information from a larger dataset. Examples of its usage include identifying and extracting specific words or phrases from a text, identifying and separating data based on a specific pattern, and cleaning and organizing data. Overall, `str_match` provides a powerful tool for data exploration and manipulation in R.

Use `str_match` in R (With Examples)

The `str_match()` function from the package in R can be used to extract matched groups from a string.

This function uses the following syntax:

```
str_match(string, pattern)
```

where:

string: Character vector **pattern:** Pattern to look for

The following examples show how to use this function in practice

Example 1: Use `str_match` with Vector

The following code shows how to use the `str_match()` function to extract matched patterns from a character vector:

```
library(stringr)
```

```
#create vector of strings
```

```
x <- c('Mavs', 'Cavs', 'Heat', 'Thunder', 'Blazers')
```

```
#extract strings that contain 'avs'
```

```
str_match(x, pattern='avs')
```

```
"avs"
```

```
"avs"
```

```
NA
```

```
NA
```

```
NA
```

The result is a matrix in which each row displays the matched pattern or an NA value if the pattern was not found.

For example:

The pattern 'avs' was found in the first element 'Mavs', so 'avs' was returned. The pattern 'avs' was found in the second element 'Cavs', so 'avs' was returned. The pattern 'avs' was not found in the third element 'Heat' so NA was returned.

And so on.

Example 2: Use `str_match` with Data Frame

Suppose we have the following data frame in R:

```
#create data frame
```

```
df <- data.frame(team=c('Mavs', 'Cavs', 'Heat', 'Thunder',  
'Blazers'),  
points=c(99, 104, 110, 103, 115))
```

```
#view data frame
```

```
df
```

```
team points
```

```
1 Mavs 99
```

```
2 Cavs 104
```

```
3 Heat 110
```

```
4 Thunder 103
```

```
5 Blazers 115
```

The following code shows how to use the `str_match()` function to add a new column to the data frame that either does or does not contain a matched pattern for each team name:

```
library(stringr)
```

```
#create new column
```

```
df$match <- str_match(df$team, pattern='avs')
```

```
#view updated data frame
```

```
df
```

```
team points match
```

```
1 Mavs 99 avs
```

```
2 Cavs 104 avs
```

```
3 Heat 110 <NA>
```

```
4 Thunder 103 <NA>
```

```
5 Blazers 115 <NA>
```

The new column titled `match` contains either the pattern `'avs'` or `NA`, depending on whether the pattern is found in the `team` column.
