## RECOMMENDED CITATION

stats writer (2024). *How can I use the corrwith() function in Pandas? Can you provide some examples?*. PSYCHOLOGICAL SCALES. Retrieved from <https://scales.arabpsychology.com/?p=154229>

The `corrwith()` function is a useful tool in the Pandas library that allows users to calculate the correlation between two variables in a dataset. This function takes in a column or series of values as its argument and returns a correlation value between that column and all other columns in the dataset. This can be used to quickly identify patterns and relationships between different variables in the data. To use the `corrwith()` function, simply pass in the desired column or series and specify the correlation method to be used. For example, "pearson" for Pearson correlation or "spearman" for Spearman correlation. Some examples of using the `corrwith()` function could be analyzing the correlation between a company's revenue and its marketing expenses, or the correlation between a student's grades and their study hours. In summary, the `corrwith()` function is a powerful tool for data analysis and can provide valuable insights into the relationships between variables in a dataset.

## Use `corrwith()` in Pandas (With Examples)

You can use the `corrwith()` function in pandas to calculate the pairwise correlation between numerical columns *with the same name* in two different pandas DataFrames.

This function uses the following basic syntax:

```
df1.corrwith(df2)
```

**Note:** This function is different than the `corr()` function, which is used to calculate the correlation between two numerical columns within the same DataFrame.

The following example shows how to use the `corrwith()` function in practice.

## Example: How to Use `corrwith()` in Pandas

Suppose we have the following two pandas DataFrames:

```
import pandas as pd
```

```
#create first DataFrame
```

```
df1 = pd.DataFrame({'team': ,  
'points': ,  
'assists': ,  
'rebounds': })
```

```
print(df1)
```

```
team points assists rebounds
```

```
0 A 18 4 10
```

```
1 B 22 5 6
```

```
2 C 29 5 4
```

```
3 D 25 4 6
```

```
4 E 14 8 3
```

```
5 F 11 12 5
```

```
#create second DataFrame
```

```
df2 = pd.DataFrame({'team': ,  
'points': ,
```

```
'assists': ,  
'rebs': })
```

```
print(df2)
```

```
team points assists rebs
```

```
0 A 22 15 4
```

```
1 B 25 13 11
```

```
2 C 27 8 12
```

```
3 D 35 8 8
```

```
4 E 25 5 7
```

```
5 F 20 8 10
```

We can use the `corrwith()` function to calculate the correlation between the numeric columns with the same names in the two DataFrames:

```
#calculate correlation between numeric columns with  
same names in each DataFrame
```

```
df1.corrwith(df2)
```

```
points 0.677051
```

```
assists -0.478184
```

```
rebounds NaN
```

```
rebs NaN
```

**dtype: float64**

**From the output we can see:**

**The correlation between the values in the points columns in the two DataFrames is 0.677. The correlation between the values in the assists columns in the two DataFrames is -0.478.**

**Since the column names rebounds and rebs didn't exist in both DataFrames, a value of NaN is returned for each of these columns.**

**Note # 1: By default, the `corrwith()` function calculates the Pearson correlation coefficient between columns, but you can also specify `method='kendall'` or `method='spearman'` to instead calculate a different type of correlation coefficient.**

**Note #2: You can find the complete documentation for the `corrwith()` function .**

**The following tutorials explain how to perform other common operations in pandas:**
