Splitting a column of lists into multiple columns involves using a delimiter to separate the lists into individual values and then mapping each of those values to a new column. This can be done using a variety of methods, such as SQL, Excel formulas, or programming languages. A well-defined and organized data source is essential for this process. Once the columns are separated, advanced data analysis can be performed on the individual columns.

You can use the following basic syntax to split a column of lists into multiple columns in a pandas DataFrame:

```
#split column of lists into two new columns  
split = pd.DataFrame(df.to_list(), columns = )
```

```
#join split columns back to original DataFrame  
df = pd.concat(, axis=1)
```

The following example shows how to use this syntax in practice.

Example: Split Column of Lists into Multiple Columns in Pandas

Suppose we have the following pandas DataFrame in which the column called **points** contains lists of values:

```
import pandas as pd
```

```
#create DataFrame  
df = pd.DataFrame({'team': ,  
'points': , , , })
```

```
#view DataFrame  
print(df)
```

```
team points  
0 Mavs  
1 Heat  
2 Kings  
3 Suns
```

We can use the following syntax to create a new DataFrame in which the **points** column is split into two new columns called **game1** and **game2**:

#split column of lists into two new columns

```
split = pd.DataFrame(df.to_list(), columns = )
```

```
#view DataFrame
```

```
print(split)
```

```
game1 game2
```

```
0 99 105
```

```
1 94 113
```

```
2 99 97
```

```
3 87 95
```

If we'd like, we can then join this split DataFrame back with the original DataFrame by using the **concat()** function:

#join split columns back to original DataFrame

```
df = pd.concat(, axis=1)
```

```
#view updated DataFrame
```

```
print(df)
```

```
team points game1 game2
```

```
0 Mavs 99 105
```

```
1 Heat 94 113
```

```
2 Kings 99 97
```

```
3 Suns 87 95
```

Lastly, we can drop the original **points** column from the DataFrame if we'd like:

#drop original points column

```
df = df.drop('points', axis=1)
```

```
#view updated DataFrame
```

```
print(df)
```

```
team game1 game2
```

```
0 Mavs 99 105
```

```
1 Heat 94 113
```

```
2 Kings 99 97
```

```
3 Suns 87 95
```

The end result is a DataFrame in which the original **points** column of lists is now split into two new columns called **game1** and **game2**.

Note: If your column of lists has an uneven number of values in each list, pandas will simply fill in missing values with **NaN** values when splitting the lists into columns.
